

Week 7

July 15, 2021

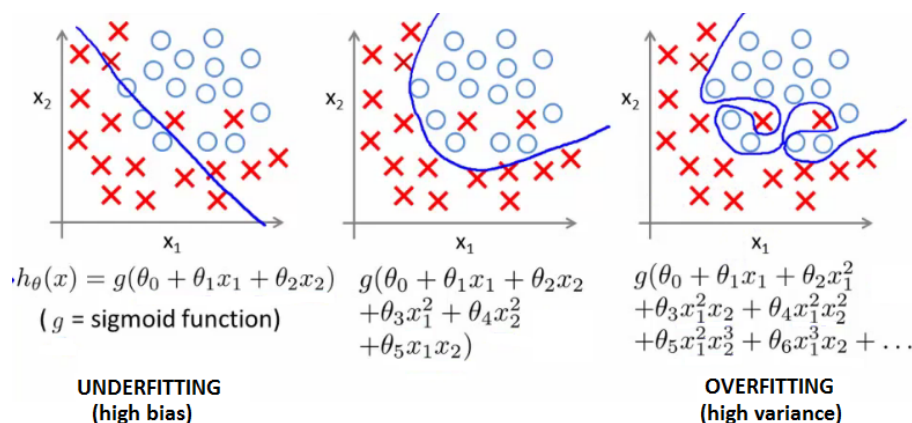

Overfitting with linear regression

- We will use our house pricing example yet another time.
- If we fit a linear function to the data, we have underfitting - also known as high bias.
- If we fit a quadratic function, it will fit better than a straight line, but it will not pass through all of the points.
- If we fit 4th order polynomial, the curve fit's through all five examples. This is overfitting - also known as high variance.

Overfitting with linear regression

- The same thing may happen with logistic regression.
- Sigmoidal function is an underfit.
- A high order polynomial, on the other hand, results in overfitting (high variance hypothesis).

Cost function optimization for regularization

Penalize and make some of the θ parameters really small.

$$\min \frac{1}{2m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) + y^{(i)})^2 + 1000\theta_3^2 + 1000\theta_4^2$$

So we simply end up with θ_3 and θ_4 being near to zero (because of the huge constants) and we're basically left with a quadratic function.

Regularization

Small parameter values correlate to a simpler hypothesis (you effectively get rid of some of the terms). Overfitting is less likely with a simpler hypothesis.

$$J(\theta) = \frac{1}{2m} \left[\sum_{i=1}^m (h_{\theta}(x^{(i)}) + y^{(i)})^2 + \lambda \sum_{j=1}^m \theta_j^2 \right]$$

λ is the regularization parameter that controls a trade off between our two goals:

- Want to fit the training set well.
- Want to keep parameters small.

Later in the course, we'll look at various automated methods for selecting λ .

Regularized linear regression

Algorithm 1 Regularized linear regression

```
1: while not converged do
2:    $\theta_j := \theta_j - \alpha \left[ \frac{1}{m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) + y^{(i)}) x_j^{(i)} + \frac{\lambda}{m} \theta_j \right]$ 
3:   (for  $j = 1, 2, 3, \dots, n$ )
```

Regularization with the normal equation

$$\Theta = (X^T X + \lambda \underbrace{\begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}}_{(n+1) \times (n+1)})^{-1} X^T y$$

e.g. if $n = 2$ $\begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}$

Regularized logistic regression

Logistic regression cost function is as follows:

$$J(\theta) = -\left[\frac{1}{m} \sum_{i=1}^m y^{(i)} \log(h_{\theta}(x^{(i)})) + (1 - y^{(i)}) \log(1 - h_{\theta}(x^{(i)}))\right] + \frac{\lambda}{2m} \sum_{j=1}^m \theta_j^2$$

Algorithm 2 Regularized logistic regression

- 1: **while** not converged **do**
 - 2: $\theta_j := \theta_j - \alpha \left[\frac{1}{m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)}) x_j^{(i)} + \frac{\lambda}{m} \theta_j \right]$
 - 3: (for $j = 1, 2, 3, \dots, n$)
-

It appears to be the same as linear regression, except that the hypothesis is different.
